Description

Setting device, particularly a motor vehicle parking brake

The invention relates to a setting device, particularly a motor vehicle parking brake in accordance with claim 1 or claim 22.

An actuation mechanism for a brake with a brake cable which can be operated by an actuator via a spindle shaft and with a force sensor for determining the mechanical loading of the brake cable on application of the brake is known from DE 101 02 685 A1, in which the mechanical load on the brake cable via the actuator, decoupled from the brake cable, can be determined. The force sensor contains a spring screw arranged axially between the brake side end of the spindle shaft and a housing accommodating the actuation mechanism, of which the change in length on actuation of the spindle shaft to apply the brake is measured by a Hall chip within the spring screw and serves as a measure for the force exerted on the brake cable when the brake is applied.

According to the object of the present invention, using a mechanism of the type described above as its starting point, a setting device is to be created which stands out by virtue of its compact design and makes it possible in a simple manner also to measure the brake cable force when the brake is released, especially if blocking occurs.

The aforementioned object is achieved by a setting device in accordance with claim 1 or 23; Advantageous embodiments are the object of the subclaims.

2

The arrangement of the elastic element in the area of the hollow shaft, especially in the form of a spring screw concentrically surrounding the hollow shaft and the spindle shaft, allows a compact design, in particular an axial design, to be easily achieved.

By embodying the at least one elastic element both as a compression spring element and also as a tension spring element, a force measurement and thereby brake cable monitoring is advantageously made possible both on application and also on release of the brake; In accordance with an advantageous embodiment of the invention, it is possible to separate the application force measurement from the release force measurement while retaining a compact design by using two spring screws arranged concentrically to each other. A further separation option while retaining a compact design is advantageously possible by arranging the second elastic element in the space to be kept free for the lifting movement of the spindle shaft, with the end of the spindle shaft being able to penetrate into the interior of the elastic element embodied as the spring screw.

The parallel, especially concentric, compact and simple design provided by the arrangement of the at least one elastic element can be even further refined by a force sensor receiver assigned to the force sensor emitter moved on axial deformation of the support being able to be fixed or contacted in the vicinity of the telescopic device, e.g. integrated on a shared circuit board, without the need for longer lines laid to provide flexibility.

The invention as well as further advantageous embodiments in accordance with features of the subclaims are explained in more detail below with reference to schematic exemplary embodiments in the drawing; The Figures show:

- FIG. 1 an inventive setting device in a perspective axial part longitudinal section;
- FIG. 2 the setting device shown in Fig. 1 with the control unit and force sensor unit removed for the sake of clarity;
- FIG. 3, 4 the setting device according to Fig. 1 with the brake cable applying the brake in an overall axial longitudinal section and in an enlarged section in the force sensor area;
- FIG. 5, 6 the setting device according to FIG. 3, 4 with the brake cable released in a overall axial longitudinal cross section and in an enlarged section in the force sensor area;
- FIG. 7, 8 the setting device according to FIG. 1 in the brake setting with a first elastic element for brake application sensing and second elastic element supported axially to it for brake release sensing in an overall axial longitudinal cross section and in an enlarged section in the force sensor area;
- FIG. 9, 10 the setting device according to FIG. 7, 8 with a brake cable blocked on attempted release in an

4

overall axial longitudinal cross section and in an enlarged section in the force sensor area;

FIG. 11, 12 the setting device to FIG. 1 in the brake setting with a first elastic element for brake application sensing and a second elastic element concentric with it for brake release sensing in an overall axial longitudinal cross section and in an enlarged section in the force sensor area;

FIG. 13, 14 the setting device according to FIG. 11, 12 with a brake cable blocked on attempted release in an overall axial longitudinal cross section and in an enlarged section in the force sensor area;

FIG. 15, 16 the setting device in accordance with FIG. 1 with a single elastic element for brake release sensing with the brake cable applied in an overall axial longitudinal cross section and in an enlarged section in the force sensor area;

FIG. 17, 18 the setting device in accordance with FIG. 15, 16 with the brake cable blocked on attempted release in an overall axial longitudinal cross section and in an enlarged section in the force sensor area.

The following major components of the inventive setting device are accommodated by a housing 1 with an axially enclosing housing cover 1.1: An axially movable telescopic unit 2;3 containing a hollow shaft 2 and a spindle shaft 3 connected to this in a manner that allows it to rotate and advance and actuate a brake cable 4, as well as a setting unit 10 for the

ENGLISH TRANSLATION OF THE INTERNATIONAL APPLICATION
FOR NATIONAL PHASE SUBMISSION

5

telescopic unit 2;3 with an electric motor 8, which, with a worm shaft 8.2 as part of its rotor shaft 8.1, drives a transmission gear wheel 2.1 which can be moved axially to it and is connected in a fixed manner to the hollow shaft 2 in a fixed drive connection via an intermediate gear wheel 11.

An elastic element 5 in the form of a spring screw concentrically enclosing the hollow shaft 2 or the spindle shaft 3 is provided as the advancing support for the hollow shaft 2, which as a compression spring rests with one of its ends via an axial thrust washer 9 against a shoulder of the housing 1 and with its other axial end on a force sensor emitter 2.2 with a fixed connection to the hollow shaft 2.

When the telescopic device 2; 3 is driven in the sense of a movement of the brake cable 4 to the right, i.e. in the sense of applying a motor vehicle parking brake not shown in any greater detail here, the elastic element 5 is compressed by being pressed against the axial bearing 9; Simultaneously, in accordance with the compression of the elastic element, the force sensor emitter 2.2. moves to the left; the distance covered here is thus a measure of the application force or brake force exerted on the brake cable 4 by the electric motor 8 via the gearing, the hollow shaft 2 and the spindle shaft 3.

In addition to the force sensor emitter 2.2, especially in the form of a ferromagnetic disk, a force sensor receiver 7.1 assigned to this emitter, especially in the form of a Hall chip, serves to determine the spring path during the support compression of the elastic element 5, especially in the form of spring screw. The force sensor receiver 7.1 is designed for

FOR NATIONAL PHASE SUBMISSION

6

simple manufacturing without the need for flexible lines and designed to exploit the compact available free space in the area of the elastic element 5 within the housing 1 - as can especially be seen from FIG.2 - and an integrated component of a control unit 7.2; 7.3 for the setting device 10 preferably containing further electrical or electronic components 7.2 or 7.3, preferably accommodated on a control unit circuit board 7.

The constructive or functional relationship of the components described in basic terms above is explained in greater detail below with reference to different operating states of a parking brake when the brake is applied and/or released.

FIG.3 shows an inventive setting device for a motor vehicle parking brake in the brake position with the brake applied, i.e. the brake cable 4 moved to the right; to do this a torque is transmitted from the electric motor 8 via its worm shaft 8.2 via the intermediate gear wheel 11 to the transmission drive wheel 2.1 permanently connected to the hollow shaft 2 functioning concentrically with it as a spindle nut. An axial advancing movement is exerted on this spindle shaft 3 via the inner thread of the hollow shaft 2 via the outer thread of the spindle shaft 3 which meshes with it in the sense of an application of the parking brake by the brake cable 4. When the brake cable applies the brake 4 through the movement of the spindle shaft 3 into the brake setting shown in FIG. 3, the hollow shaft 2 is supported on the housing 1 via the elastic element 1 in the form of a spring screw concentrically surrounding the hollow shaft 2 or the inner meshing spindle

ENGLISH TRANSLATION OF THE INTERNATIONAL APPLICATION
FOR NATIONAL PHASE SUBMISSION

7

shaft 3; to this end the elastic element, preferably as a compression spring, lies with its right-hand free end on the force sensor emitter 2.2 preferably permanently connected to the hollow shaft 2 and with its left-hand end via an axial thrust washer 9 on a shoulder of the housing 1.

When the brake cable 4 is pulled on the elastic element 5 is compressed in proportion to the force exerted here on the brake cable 4 via the spindle shaft 3; the hollow shaft 2 or the gearing drive wheel 2.1 permanently connected to it is in this case accordingly able to be moved axially relative to the intermediate gear wheel 11. The path corresponding to this compression deformation of the elastic element 5 is - according to the enlarged section in FIG.4 - recorded as the dimension a_1 between the force sensor emitter 2.2 which is also moved on the one hand and the assigned, force sensor receiver 7.1 which remains stationary and is recorded in the control unit advantageously also arranged on the same control unit circuit board 7 for the setting unit 10 and processed into a representative brake force measurement variable.

FIG.5 shows the setting device according to FIG. 3 with released parking brake with spindle shaft 3 with brake cable 4 correspondingly moved into a left-hand release position; There is no load on the elastic element 5, correspondingly - according to the enlarged section in FIG.6 - the force sensor emitter 2.2 has increased its distance to the force sensor receiver 7.1 to a dimension a_2 .

As additions to the previous examples, FIG.7, 8 or FIG.9, 10 show a second elastic element 6 which is assigned to the

ENGLISH TRANSLATION OF THE INTERNATIONAL APPLICATION
FOR NATIONAL PHASE SUBMISSION

8

release movement of the brake cable 4 and which monitors the cable for a correct execution sequence, especially for detection of a blocking case.

FIG. 7, 8 show a correct brake setting with the spindle shaft 3 moved into a right-hand brake setting in accordance with FIG. 7 and a dimension a1 corresponding to a defined pressure load of the first elastic element 5 between the force sensor emitter 2.2 on the one side and the force sensor receiver 7.1 on the other side according to FIG. 8. The second elastic element 6 is not subject to any load. A compact design is achieved by the right-hand end of the spindle shaft 3 being able to move within a spring screw provided as an elastic element 6 and thereby advantageously no additional space being needed.

FIG 9, 10 now explain an attempt to release the brake when blocking of the brake cable 4 has occurred - e.g. caused by it icing up. In the attempted release the spindle shaft 3 and the hollow shaft 2 move by a small amount - documented by the difference of the dimension a1 according to FIG. 8 compared to the dimension a2 according to FIG. 10, with the hollow shaft 2 hitting the second elastic element 6 and causing this to compress and a defined force analysis being enabled via the processing of the dimension a2.

FIG. 11, 12 or FIG. 13, 14 show a further inventive embodiment with a first elastic element 5 for measuring brake application force and also a second elastic element 6 for measuring brake release force. Both elastic elements are embodied as screw springs and engage concentrically to each other with the

ENGLISH TRANSLATION OF THE INTERNATIONAL APPLICATION
FOR NATIONAL PHASE SUBMISSION

9

hollow shaft 2 or the spindle shaft 3 in a compact design in the area of the control unit 7.2; 7.3.

FIG. 11 shows the brake setting with the spindle shaft 3 driven to the right into its end brake setting and according to FIG. 12 with the corresponding dimension a1 between the force sensor emitter 2.2 on one side and the assigned force sensor receiver 7.1 on the other side. The second elastic element 6 is in this case connected in parallel to the first elastic element 5 in order to have the same effect, however according to one embodiment of the invention is provided with a different spring characteristic such that a support for the advancing movement resulting from the spring force compression only remains if, as assumed in FIG. 13, 14 - e.g. by reversing the direction of rotation of the electric motor - the drive of the hollow shaft 2 and the spindle shaft 3 is undertaken in the sense of a brake release movement of the brake cable 4 and through this the larger dimension a2 according to FIG. 14 is produced. As can be seen from FIG. 11, at the right-hand end of the hollow shaft 2 there is a stop, especially provided on the housing cover 1.1, by which it is possible to prevent the axial movement of the hollow shaft 2 exceeding the maximum spring travel of the second elastic element 6; through a corresponding axial play before the stop of the hollow shaft 2 a clear identification of the zero point between the end of the loading of the first elastic element 5 and the continuing load pressure on the second elastic element 6 on transition to the release attempt according to FIG. 13, 14 is possible in a simple manner; A further clarification is provided according

ENGLISH TRANSLATION OF THE INTERNATIONAL APPLICATION
FOR NATIONAL PHASE SUBMISSION

10

to an embodiment by selecting different elasticity or spring constants of the elastic element 5 or 6.

FIG. 15, 16 or FIG. 17, 18 show the inventive solution according to claim 22 for a setting direction with only one monitoring of the release movement of the parking brake.

FIG. 15 additionally shows the spindle shaft 8 in its right-hand brake setting with brake cable 4 pulled on. The hollow shaft 2 is supported via the force sensor emitter 2.2 and the axial bearing 9 on the housing 1; the corresponding dimension a_1 is also specified in the enlarged section according to FIG.16.

FIG.17, 18 illustrate the detection of blocking of the brake cable 3 when an attempt is made to release the brake. The blocked brake cable 4 presses the spindle shaft 3 as well as the hollow shaft 2 to the right against the elastic element 5; accordingly the force sensor emitter 2.2 moves by the increased dimension a_2 in relation to the force sensor receiver 7.2. Force sensor-receiver 7.2 and hollow shaft 2 in this case no longer rest against the left-hand shoulder of the housing 1.

The invention relates to a setting device, especially for a motor vehicle parking brake, with a telescopic device 2; 3 containing a hollow shaft 2 a spindle shaft 3 with an axial rotary advancing connection to it which operates a brake cable 4 movable axially in a housing or such like, as well as with an axial advancing movement support between the hollow shaft 2 and the housing 1 via at least one elastic element 5, which

ENGLISH TRANSLATION OF THE INTERNATIONAL APPLICATION
FOR NATIONAL PHASE SUBMISSION

11

serves as a force sensor for a brake application or a blocked brake release; according to one embodiment a second elastic element 6 is provided for blocking detection of the brake cable 4 on an attempt to release the brake and according after the tension on the first elastic element 5 is released.
